1 CHEMISTRY

- Express the problem of balancing the following chemical equation as a matrix equation.

Solution: Let the balanced version of (1.1.1) be

which results in the following equations

$$\begin{aligned} (x_1 - 3x_3) Fe &= 0 \\ (2x_2 - 2x_4) H &= 0 \\ (x_2 - 4x_3) O &= 0 \end{aligned} \quad (1.1.3)$$

which can be expressed as

$$\begin{aligned} x_1 + 0x_2 - 3x_3 + 0x_4 &= 0 \\ 0x_1 + 2x_2 + 0x_3 - 2x_4 &= 0 \\ 0x_1 + x_2 - 4x_3 + 0x_4 &= 0 \end{aligned} \quad (1.1.4)$$

resulting in the matrix equation

$$\begin{pmatrix} 1 & 0 & -3 & 0 \\ 0 & 2 & 0 & -2 \\ 0 & 1 & -4 & 0 \end{pmatrix} \mathbf{x} = \mathbf{0} \quad (1.1.5)$$

where

$$\mathbf{x} = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} \quad (1.1.6)$$

- Solve (1.1.2) by row reducing the matrix in (1.1.5).

Solution: (1.1.5) can be row reduced as follows

$$\begin{pmatrix} 1 & 0 & -3 & 0 \\ 0 & 2 & 0 & -2 \\ 0 & 1 & -4 & 0 \end{pmatrix} \xrightarrow{R_2 \leftrightarrow R_3} \begin{pmatrix} 1 & 0 & -3 & 0 \\ 0 & 1 & 0 & -1 \\ 0 & 1 & -4 & 0 \end{pmatrix} \quad (1.2.1)$$

$$\xrightarrow{R_3 \leftarrow R_3 - R_2} \begin{pmatrix} 1 & 0 & -3 & 0 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & -4 & 1 \end{pmatrix} \quad (1.2.2)$$

$$\xrightarrow{R_1 \leftarrow 4R_1 - 3R_3} \begin{pmatrix} 4 & 0 & 0 & -3 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & -4 & 1 \end{pmatrix} \quad (1.2.3)$$

$$\xrightarrow{\begin{matrix} R_1 \leftarrow \frac{1}{4} \\ R_3 \leftarrow -\frac{1}{4}R_3 \end{matrix}} \begin{pmatrix} 1 & 0 & 0 & -\frac{3}{4} \\ 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & -\frac{1}{4} \end{pmatrix} \quad (1.2.4)$$

Thus,

$$x_1 = \frac{3}{4}x_4, x_2 = x_4, x_3 = \frac{1}{4}x_4 \quad (1.2.5)$$

$$(1.2.6)$$

$$\Rightarrow \mathbf{x} = x_4 \begin{pmatrix} \frac{3}{4} \\ 1 \\ \frac{1}{4} \\ 1 \end{pmatrix} = \begin{pmatrix} 3 \\ 4 \\ 1 \\ 4 \end{pmatrix} \quad (1.2.7)$$

upon substituting $x_4 = 4$. (1.1.2) then becomes

3. Verify your answer through a python code.

Solution: Execute

codes/chembal.py

2 MATHEMATICS

1. Find the equation of the plane P that contains the point $\begin{pmatrix} 1 \\ -1 \\ 2 \end{pmatrix}$ and is perpendicular to each of the planes

$$P_1 : (2 \ 3 \ -2)\mathbf{x} = 5 \quad (2.1.1)$$

$$P_2 : (1 \ 2 \ -3)\mathbf{x} = 8 \quad (2.1.2)$$

From (2.1.1), the normals to P_1, P_2 are

$$\mathbf{n}_1 = (2 \ 3 \ -2) \quad (2.1.3)$$

$$\mathbf{n}_2 = (1 \ 2 \ -3)$$

$\therefore P \perp P_1, P \perp P_2$, if \mathbf{n} be the normal to P , $\mathbf{n} \perp \mathbf{n}_1, \mathbf{n} \perp \mathbf{n}_2$, which can be expressed using (2.1.3) as

$$\begin{pmatrix} 2 & 3 & -2 \\ 1 & 2 & -3 \end{pmatrix} \mathbf{n} = 0 \quad (2.1.4)$$

Obtain \mathbf{n} using row reduction.

2. Verify your answer through a python code.

3. Verify that $\mathbf{n} = \mathbf{n}_1 \times \mathbf{n}_2$.

3 PHYSICS

1. A force of $\mathbf{F} = 7\hat{i} + 3\hat{j} - 5\hat{k}$ acts on a particle whose position vector is $\mathbf{r} = \hat{i} - \hat{j} + \hat{k}$. Find the torque about the origin given by $\mathbf{F} \times \mathbf{r}$ using a matrix equation.

2. Verify your answer using python.

4 GATE PROBLEMS

1. For an LTI system, the Bode plot for its gain is as illustrated in the figure shown. The number of system poles N_p and number of system zeros N_z in the frequency range $1 \text{ Hz} \leq f \leq 10^7 \text{ Hz}$ is

Solution:-

Let us consider a generalized transfer gain

$$H(s) = k \frac{(s-z_1)(s-z_2)\dots(s-z_{m-1})(s-z_m)}{(s-p_1)(s-p_2)\dots(s-p_{n-1})(s-p_n)}$$

$$\text{Gain} = 20\log|H(s)| = 20\log|k| + 20\log|s - z_1| +$$

$$20\log|s - z_2| + \dots + 20\log|s - z_m| - 20\log|s - p_1| - 20\log|s - p_2| - \dots - 20\log|s - p_n|$$

- When a pole is encountered the slope always decreases by -20 dB/decade
- When a zero is encountered the slope always increases by +20 dB/decade
- At $f = 10 \text{ Hz}$, change in slope = -20dB/sec, Hence we have 1 pole here
- At $f = 10^2 \text{ Hz}$, Change in slope = -40dB/sec, Hence we have 2 poles here
- At $f = 10^3 \text{ Hz}$, Change in slope = +20dB/sec, Hence we have 1 zero here
- At $f = 10^4 \text{ Hz}$, Change in slope = +40dB/sec, Hence we have 2 zeros here
- At $f = 10^5 \text{ Hz}$, Change in slope = -40dB/sec, Hence we have 2 poles here
- At $f = 10^6 \text{ Hz}$, Change in slope = -20dB/sec, Hence we have 1 pole here

$$N_p = 6 \quad (4.1.1)$$

$$N_z = 3 \quad (4.1.2)$$

2. Consider the following second order system with the transfer function:

$$G(s) = \frac{1}{1 + 2s + s^2}$$

with input unit step

$$R(s) = \frac{1}{s}$$

Let $C(s)$ be the corresponding output. The time

taken by the system output $c(t)$ to reach 94% of its steady state value, rounded off to two decimal places is

- a) 5.25
- b) 4.50
- c) 2.81
- d) 3.89

Solution:- The approach for finding the solution is as follows:

- finding $C(s)$
- finding $c(t)$
- finding the time at which $c(t)$ attains 94% of its steady state value

We are given $G(s)$ and $R(s)$, to find $C(s)$, we can simply multiply these two

$$C(s) = R(s).G(s) = \left(\frac{1}{s}\right)\left(\frac{1}{1+2s+s^2}\right)C(s) = \frac{1}{s(1+s)^2} \quad (4.2.1)$$

To find $c(t)$, we have to do inverse Laplace transform on $C(s)$

$$c(t) \longleftrightarrow C(s)$$

Inverse Laplace transform can be calculated by the formula:

$$f(t) = \frac{1}{2\pi j} \int_{a-j\infty}^{a+j\infty} F(s)e^{st} ds$$

From the above formula, the inverse Laplace for some common expressions are:

$$u(t) \longleftrightarrow \frac{1}{s}$$

$$e^{-at}u(t) \longleftrightarrow \frac{1}{s+a}$$

$$te^{-at}u(t) \longleftrightarrow \frac{1}{(s+a)^2}$$

We found $C(s)$ as:

$$C(s) = \frac{1}{s(1+s)^2}$$

Now, we will use partial fractions to make applying Inverse Laplace easy.

$$C(s) = \frac{1}{s(1+s)^2} = \frac{A}{s} + \frac{B}{(1+s)} + \frac{C}{(1+s)^2}$$

We get,

$$\begin{aligned} A &= 1 & A+B &= 0 & 2A+B+C &= 0 \\ A &= 1 & B &= -1 & C &= -1 \end{aligned}$$

Therefore,

$$C(s) = \frac{1}{s} - \frac{1}{(1+s)} - \frac{1}{(1+s)^2}$$

$$c(t) = L^{-1}\left(\frac{1}{s} - \frac{1}{(1+s)} - \frac{1}{(1+s)^2}\right)$$

From the properties of inverse Laplace transform,

$$\begin{aligned} L^{-1}(F_1(s) + F_2(s) + F_3(s)) &= L^{-1}(F_1(s)) \\ &+ L^{-1}(F_2(s)) + L^{-1}(F_3(s)) \end{aligned}$$

Therefore;

$$c(t) = L^{-1}\left(\frac{1}{s}\right) - L^{-1}\left(\frac{1}{(1+s)}\right) - L^{-1}\left(\frac{1}{(1+s)^2}\right)$$

Using the Known inverse transforms:

$$c(t) = (1 - e^{-t} - te^{-t}).u(t)$$

To know the steady state value of $c(t)$, we calculate

$$\lim_{t \rightarrow \infty} c(t) = (1 + 0 + 0).(1) = 1$$

Now, 94% of 1 is 0.94, so we should now solve for a positive t such that

$$(1 - e^{-t} - te^{-t}) = 0.94$$

After calculation, t turns out to be

$$t = 4.5221$$

Therefore, answer is option (b) We can also find the solution by plotting $c(t)$:

3. The block diagram of a system is illustrated in the figure shown, where $X(s)$ is the input and $Y(s)$ is the output. The transfer function $H(s) = \frac{Y(s)}{X(s)}$ is

(A) $H(s) = \frac{s^2+1}{s^3+s^2+s+1}$

(B) $H(s) = \frac{s^2+1}{s^3+2s^2+s+1}$

(C) $H(s) = \frac{s^2+1}{s^2+s+1}$

(D) $H(s) = \frac{s^2+1}{2s^2+1}$

Solution:- Here we have two transfer function

s and $\frac{1}{s}$ in parallel with a adder as shown in figure. After solving these two parallel transfer function by just adding both of them we will get

Now we will convert three input adder into two input adder as shown in figure given below.

Now we have Negative Unity Feedback System (NUFS) in closed loop transfer function.

Let's say we have transfer function $G(s)$ with Negative Unity Feedback System in closed loop then we will solve this by

$$\frac{G(s)}{1+G(s)}$$

Here we have

Here we have two transfer function in series

Now we have one more transfer function with negative unity feedback.

Again we will solve this then we will get

Now

$$X(s) \left(\frac{s^2+1}{s^3+2s^2+s+1} \right) = Y(s)$$

$$\frac{Y(s)}{X(s)} = \frac{s^2+1}{s^3+2s^2+s+1}$$

The correct option is (B)

4. Let the state-space representation of an LTI system be.

$$\dot{x}(t) = Ax(t) + Bu(t)$$

$$y(t) = Cx(t) + Du(t)$$

A,B,C are matrices, D is scalar, u(t) is input to the system and y(t) is output to the system. let

$$b1 = \begin{bmatrix} 0 & 0 & 1 \end{bmatrix}$$

$$b1^T = B$$

and D=0. Find A and C.

$$H(s) = \frac{1}{s^3 + 3s^2 + 2s + 1}$$

Solution:- STATE MODEL

Let U1(t) and U2(t) are the inputs of the MIMO system and y1(t),y2(t) are the output of the system and x1(t) and x2(t) are the state variables.

so output equation is,

$$y1(t) = C_{11} \times x1(t) + C_{12} \times x2(t) + d_{11} \times U1(t) + d_{12} \times U2(t) \quad (4.4.1)$$

$$y2(t) = C_{21} \times x1(t) + C_{22} \times x2(t) + d_{21} \times U1(t) + d_{22} \times U2(t) \quad (4.4.2)$$

$$\begin{bmatrix} y1(t) \\ y2(t) \end{bmatrix} = \begin{bmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{bmatrix} \times \begin{bmatrix} x1(t) \\ x2(t) \end{bmatrix} + \begin{bmatrix} d_{11} & d_{12} \\ d_{21} & d_{22} \end{bmatrix} \times \begin{bmatrix} U1(t) \\ U2(t) \end{bmatrix}$$

therefore Y(t)=C.X(t)+D.U(t)

$$x1'(t) = a_{11} \times x1(t) + a_{12} \times x2(t) + b_{11} \times U1(t) + b_{12} \times U2(t) \quad (4.4.3)$$

$$x2'(t) = a_{21} \times x1(t) + a_{22} \times x2(t) + b_{21} \times U1(t) + b_{22} \times U2(t) \quad (4.4.4)$$

$$\begin{bmatrix} x1'(t) \\ x2'(t) \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \times \begin{bmatrix} x1(t) \\ x2(t) \end{bmatrix} + \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \times \begin{bmatrix} U1(t) \\ U2(t) \end{bmatrix}$$

therefore $\dot{X}(t) = A.X(t) + B.U(t)$

5. FINDING TRANSFER FUNCTION

So, $\dot{X}(t) = A.X(t) + B.U(t)$ be equation 1

and $Y(t) = C.X(t) + D.U(t)$ be equation 2

by applying laplace transforms on both sides of equation 1

we get

$$S.X(S) - X(0) = A.X(S) + B.U(S)$$

$$S.X(S) - A.X(S) = B.U(S) + X(0)$$

$$(SI - A)X(S) = X(0) + B.U(S)$$

$$X(S) = X(0)([SI - A])^{-1} + B.([SI - A])^{-1}.U(S)$$

Laplace transform of equation 2 and sub X(s)

$$Y(S) = C.X(S) + D.U(S)$$

$$Y(S) = C.[X(0)([SI - A])^{-1} + B.([SI - A])^{-1}.U(S)] + D.U(S)$$

If X(0)=0

$$\text{then } Y(S) = C.[B.([SI - A])^{-1}.U(S)] + D.U(S)$$

$$\frac{Y(S)}{U(S)} = C.[B.([SI - A])^{-1}] + D = H(S)$$

As we know that

$$Y(s) = H(s) \times U(s) = \left(\frac{1}{s^3 + 3s^2 + 2s + 1} \right) \times U(s)$$

$$\text{let } X(S) = \frac{U(S)}{\text{denominator}}$$

$$Y(S) = X(S) \times \text{numerator}$$

$$s^3 X(s) + 3s^2 X(s) + 2s X(s) + X(s) = U(S)$$

$$\begin{bmatrix} sX(s) \\ s^2 X(s) \\ s^3 X(s) \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -1 & -2 & -3 \end{bmatrix} \times \begin{bmatrix} X(s) \\ sX(s) \\ s^2 X(s) \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \times U$$

$$\text{therefore } A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -1 & -2 & -3 \end{bmatrix}$$

Since $Y(S) = X(S) \times \text{numerator}$
therefore $Y(S) = X(S)$;

$$Y = \begin{bmatrix} 1 & 0 & 0 \end{bmatrix} \times \begin{bmatrix} x(s) \\ sx(s) \\ s^2x(s) \end{bmatrix}$$

$$C = \begin{bmatrix} 1 & 0 & 0 \end{bmatrix}$$

6. Consider a unity feedback system as shown in the figure, shown with an integral compensator k/s and open-loop transfer function

$$G(s) = \frac{1}{s^2+3s+2}$$

where $k > 0$. The positive value of k for which there are two poles of unity feedback system on $j\omega$ axis is equal to—(rounded off to two decimal places)

Solution:- A transfer function is the relative function between input and output.

In a negative feedback system an intermediate signal is defined as Z .

$$Y(s) = Z(s) \cdot G(s)$$

$$Z(s) = X(s) - Y(s) \cdot H(s) \Rightarrow X(s) = Z(s) + Y(s) \cdot H(s)$$

$$X(s) = Z(s) + Z(s) \cdot G(s) \cdot H(s)$$

$$\frac{Y(s)}{X(s)} = \frac{Z(s) \cdot G(s)}{Z(s) + Z(s) \cdot G(s) \cdot H(s)}$$

So, the transfer function of negative feedback is

$$\frac{G(s)}{1 + G(s) \cdot H(s)}$$

Since unit feedback $H(s) = 1$
Now the transfer function of unity negative feedback is $\frac{G(s)}{1 + G(s)}$

The net transfer function in the given

7. is.....

$$\frac{Y(s)}{X(s)} = \frac{G(s) \cdot k/s}{1 + G(s) \cdot k/s}$$

The characteristic equation is $1 + (G(s) \cdot k/s) = 0$

that is..,

$$C.E = 1 + \frac{k}{s(s^2+3s+2)} = 0 \Rightarrow s(s^2+3s+2) + k = 0$$

$$\Rightarrow s^3 + 3s^2 + 2s + k = 0$$

Routh-Hurwitz Criterion:-

This criterion is based on arranging the coefficients of characteristic equation into an array called Routh array.

$$q(s) = a_0s^n + a_1s^{n-1} + a_2s^{n-2} + \dots + a_{n-1}s + a_n = 0$$

$$\begin{vmatrix} s^n & a_0 & a_2 & a_4 & \dots \\ s^{n-1} & a_1 & a_3 & a_5 & \dots \\ s^{n-2} & b_1 & b_2 & b_3 & \dots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{vmatrix} \quad (4.7.1)$$

where

$$b_1 = \frac{a_1a_2 - a_0a_3}{a_1} \quad b_2 = \frac{a_1a_4 - a_0a_5}{a_1} \quad (4.7.2)$$

$$c_1 = \frac{b_1a_3 - a_1b_2}{b_1} \quad c_2 = \frac{b_1a_5 - a_1b_3}{b_1} \quad (4.7.3)$$

For poles to lie on imaginary axis any one entire row of Hurwitz matrix should be zero.

For the given characteristic equation

$$= s^3 + 3s^2 + 2s + k = 0 \quad (4.7.4)$$

$$\begin{vmatrix} s^3 & 1 & 2 \\ s^2 & 3 & k \\ s^1 & \frac{6-k}{3} & 0 \\ s^0 & k & 0 \end{vmatrix} \quad (4.7.5)$$

For poles on $j\omega$ axis any one of the rows should be zero

$$\Rightarrow \frac{6-k}{3} = 0 \text{ or } k = 0$$

But given $k > 0$...

$$\text{therefore, } 6-k=0 \Rightarrow k = 6$$

To find the location of poles on $j\omega$ axis

Auxiliary equation of the given CE is $3s^2 + k = 0$

$$\Rightarrow 3s^2 + 6 = 0 \quad (4.7.6)$$

$$\Rightarrow s = \pm j2 \quad (4.7.7)$$

8. The output response of a system is denoted as $y(t)$, and its Laplace transform is given by

$$Y(s) = \frac{10}{s(s^2 + s + 100(2)^{0.5})} \quad (4.8.1)$$

The steady state value of $y(t)$ is

- a) $100(2)^{0.5}$
- b) $\frac{1}{10(2)^{0.5}}$
- c) $10(2)^{0.5}$
- d) $\frac{1}{100(2)^{0.5}}$

Solution:-

The final value theorem states that

$$\lim_{t \rightarrow \infty} y(t) = \lim_{s \rightarrow 0} sY(s)$$

This is valid only when $sY(s)$ has poles that lie in the negative half of the real side.

If the quadratic equation $ax^2 + bx + c$ has complex roots then the real part of those roots will be $-b/2a$

Hence, verified that the roots of $s^2 + s + 100(2)^{0.5}$ have a negative real part which is -0.5 . So, Final value theorem is applicable.

Steady state value of $y(t) =$

$$\begin{aligned} \lim_{t \rightarrow \infty} y(t) &= \lim_{s \rightarrow 0} sY(s) = \lim_{s \rightarrow 0} \frac{10s}{s(s^2 + s + 100(2)^{0.5})} \\ &= \frac{10}{100(2)^{0.5}} = \frac{1}{10(2)^{0.5}} \end{aligned}$$

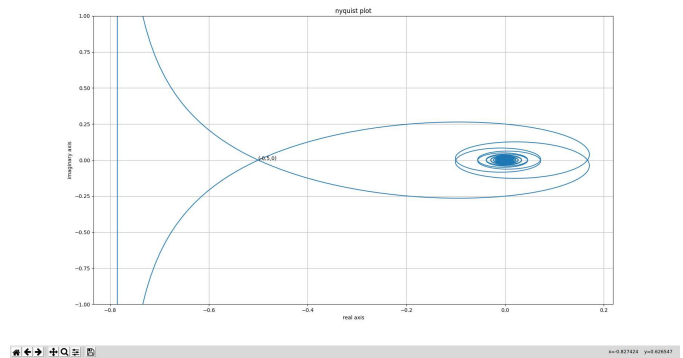

We can see that $y(t)$ is approaching a constant value 0.031 which is verifies our answer!

9. • The open loop transfer function of a unity feedback system is given by

$$G(s) = \frac{\pi e^{-0.25s}}{s}$$

in $G(s)$ plane, the Nyquist plot of $G(s)$ passes through the negative real axis at the point
(A) $(-0.5, j0)$ (B) $(-0.75, j0)$ (C) $(-1.25, j0)$
(D) $(-1.5, j0)$

Solution:-

$$G(s) = \frac{\pi e^{-0.25s}}{s}$$

Nyquist plot cuts the negative real Axis at $\omega =$ phase cross over frequency

$$G(j\omega) = \frac{\pi}{\omega} (-\sin 0.25\omega - j \cos 0.25\omega) \quad (4.9.1)$$

$$\angle G(j\omega) = -90^\circ - 0.25\omega \times 180^\circ \pi \quad (4.9.2)$$

$$\angle G(j\omega)|_{\omega=\omega_{pc}} = -180^\circ \quad (4.9.3)$$

by solving for ω we get $\omega_{pc} = 2\pi$

magnitude at any point is $X = |G(j\omega)| = \frac{\pi}{\omega}$
substituting $\omega = 2\pi$ in magnitude we get $X=0.5$

hence it intersects at $(-0.5, j0)$ so answer is A

we can verify with the following plot that it intersects at $(-0.5, j0)$

10. The characteristic equation of linear time

invariant system is given by

$$\nabla(s) = s^4 + 3s^3 + 3s^2 + s + k = 0$$

The system is BIBO stable if

A. $0 < k < \frac{12}{9}$

B. $k \leq 3$

C. $0 < k < \frac{8}{9}$

D. $k \leq 6$

Solution:-

Given data:

$$\nabla(s) = s^4 + 3s^3 + 3s^2 + s + k = 0$$

s^4	1	3	K
s^3	3	1	0
s^2	$\frac{8}{3}$	k	0
s	$(\frac{8}{3} - \frac{3K}{8}) / (\frac{8}{3})$	0	0
s^0	k	0	0

$$\Rightarrow \frac{\frac{8}{3} - 3k}{\frac{8}{3}} > 0 \quad (4.10.1)$$

$$(4.10.2)$$

$$(4.10.3)$$

$$\Rightarrow \frac{8}{3} - 3k > 0 \quad (4.10.4)$$

$$(4.10.5)$$

$$\Rightarrow 3k < \frac{8}{9} \quad (4.10.6)$$

$$(4.10.7)$$

$$\Rightarrow (0 < k < \frac{8}{9}) \quad (4.10.8)$$

for example the zeros of polynomial

$$s^4 + 3s^3 + 3s^2 + s + 0.5 = 0 \text{ are}$$

$$s_1 = -0.08373 + 0.45773i \quad (4.10.9)$$

$$s_2 = -0.08373 - 0.45773i \quad (4.10.10)$$

$$s_3 = -1.41627 + 0.55075i \quad (4.10.11)$$

$$s_4 = -1.41627 - 0.55075i \quad (4.10.12)$$

11. The asymptotic Bode magnitude plot of minimum phase transfer function $G(s)$ is show below.

Consider the following two statements.

Statement 1: Transfer function $G(s)$ has 3 poles and one zero

Statement 2: At very high frequency ($\omega \rightarrow \infty$), the phase angle $\angle G(j\omega) = -3\pi/2$

Which of the following is correct ?

(A) Statement 1 is true and Statement 2 is false.

(B) Statement 1 is false and Statement 2 is true.

(C) Both the statements are true.

(D) Both the statements are false.

Solution:- Since, each pole corresponds to -20 dB/decade and each zero corresponds to +20 dB/decade.

Therefore, from the given Bode plot we can get the Transfer equation,

$$G(s) = \frac{k}{s(1+s)(20+s)}$$

Now, from the Transfer equation we can conclude that, there are three poles (0, -1 and -20) and no zeros.

\therefore Statement 1 is false(1)

Calculating phase

Since we know that,

phase ϕ is the sum of all the phases corresponding to each pole and zero.

phase corresponding to pole is =

$$-\tan^{-1}\left(\frac{\text{imaginary}}{\text{real}}\right)$$

phase corresponding to zero is =

$$\tan^{-1}\left(\frac{\text{imaginary}}{\text{real}}\right)$$

now take,

$$s = j\omega$$
