Abstract—This manual is an introduction to control systems based on GATE problems.Links to sample Python codes are available in the text.

Download python codes using

svn co https://github.com/gadepall/school/trunk/control/codes

1 Mason's Gain Formula

1.1. The Block diagram of a system is illustrated in the figure shown, where X(s) is the input and Y(s) is the output. Draw the equivalent signal flow graph.

*The author is with the Department of Electrical Engineering, Indian Institute of Technology, Hyderabad 502285 India e-mail: gadepall@iith.ac.in. All content in this manual is released under GNU GPL. Free and open source.

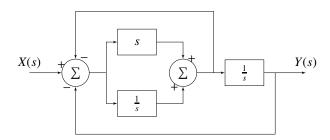

Fig. 1.1.1: signal flow block diagram

Solution: Signal flow graph of given above block diagram is

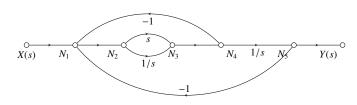

Fig. 1.1.2: signal flow graph

1.2. Draw all the forward paths and compute the respective gains. **Solution:** Here,

$$P_1 = \frac{s}{s} = 1 \tag{1.2.1}$$

$$P_2 = (1/s)(1/s) = 1/s^2$$
 (1.2.2)

Fig. 1.2.4: P₂

1.3. Draw the loops and calculate the respective gains.

Solution:

$$L_1 = (-1)(s) = -s \tag{1.3.1}$$

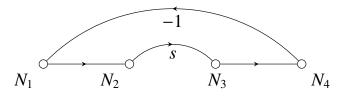

Fig. 1.3.5: L_1

$$L_2 = \frac{s}{-s} = -1 \tag{1.3.2}$$

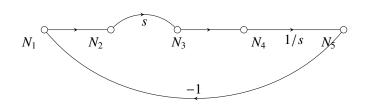

Fig. 1.3.6: L₂

$$L_3 = (\frac{1}{s}) * (-1) = \frac{-1}{s}$$
 (1.3.3)

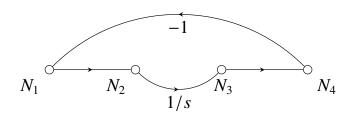

Fig. 1.3.7: L₃

$$L_4 = (\frac{1}{s})(\frac{1}{s})(-1) = \frac{-1}{s^2}$$
 (1.3.4)

1.4. State Mason's Gain formula and explain the parameters through a table.

Solution: According to Mason's Gain Formula,

$$T = \frac{Y(s)}{X(s)} \tag{1.4.1}$$

$$T = \frac{\sum_{i=1}^{N} P_i \Delta_i}{\Lambda}$$
 (1.4.2)

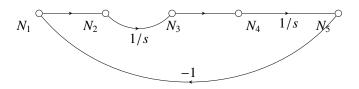

Fig. 1.3.8: L₄

1.5. Find the transfer function using Mason's Gain Formula.

Solution:

Now,

 P_i is the i^{th} forward path.

 $\Delta = 1$ - (Sum of all individual loop gains)+(sum of gain products of all possible two non-touching loops)-(sum of gain products of all possible three non-touching loops)+... Δ_i is obtained from Δ by removing the loops which are touching the i^{th} forward path.

$$\Delta = 1 - (L_1 + L_2 + L_3 + L_4)$$

$$L_1 = (-1)(s) = -s$$
 (1.5.1)

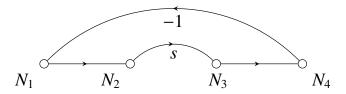

Fig. 1.5.9: L_1

$$L_2 = \frac{s}{-s} = -1 \tag{1.5.2}$$

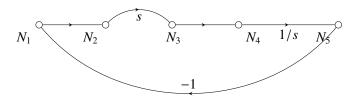

Fig. 1.5.10: L₂

$$L_3 = (\frac{1}{s}) * (-1) = \frac{-1}{s}$$
 (1.5.3)

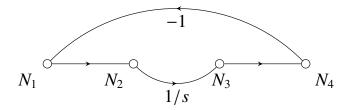

Fig. 1.5.11: L₃

$$L_4 = (\frac{1}{s})(\frac{1}{s})(-1) = \frac{-1}{s^2}$$
 (1.5.4)

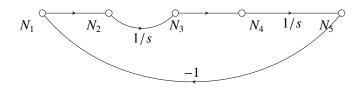

Fig. 1.5.12: L₄

$$\Delta = 1 - (-s - 1 - \frac{1}{s} - \frac{1}{s^2}) \ \Delta = \frac{s^3 + 2s^2 + s + 1}{s^2}$$

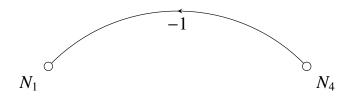

Fig. 1.5.13: Δ_1

After removing forward path from loop1 we will get Delta1

$$\Delta_1 = 1$$

Fig. 1.5.14: Δ_2

After removing forward path from loop2 we will get Delta2

$$\Delta_2 = 1$$

After removing forward path from loop3 we will get Delta4

$$\Delta_3 = 1$$

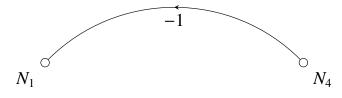

Fig. 1.5.15: Δ_3

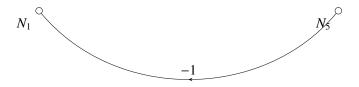

Fig. 1.5.16: Δ_4

After removing forward path from loop4 we will get Delta4

 $\Delta_4 = 1$ Here,

$$T = \frac{\sum_{i=1}^{N} (P_i)(\Delta_i)}{\Lambda}$$
 (1.5.5)

$$T = \frac{P_1 \Delta_1 + P_2 \Delta_2 + P_3 \Delta_3 + P_4 \Delta_4}{\Delta}$$
 (1.5.6)

$$T = \frac{1 * 1 + (\frac{1}{s^2}) * 1 + 0 * 1 + 0 * 1}{\frac{s^3 + 2s^2 + s + 1}{s^2}}$$
 (1.5.7)

$$H(s) = \frac{s^2 + 1}{s^3 + 2s^2 + s + 1}$$
 (1.5.8)

2 Bode Plot

2.1 Introduction

2.1. For an LTI system, the Bode plot for its gain defined as

$$G(s) = 20 \log |H(s)|$$
 (2.1.1)

is as illustrated in the Fig. 2.1. Express G(f) in terms of f.

Fig. 2.1

Solution:

$$G(f) = \begin{cases} 100 & 0 < f < 10^{1} \\ 120 - 20\log(f) & 10 < f < 10^{2} \\ 200 - 60\log(f) & 10^{2} < f < 10^{3} \\ 140 - 40\log(f) & 10^{3} < f < 10^{4} \\ -20 & 10^{4} < f < 10^{5} \\ 180 - 40\log(f) & 10^{5} < f < 10^{6} \\ 300 - 60\log(f) & 10^{6} < f < 10^{7} \end{cases}$$

(2.1

2.2. Express the slope of G(f) in terms of f. **Solution:** The desired slope is

$$\nabla G(f) = \frac{d(G(f))}{d(\log(f))}$$
 (2.2.1)

$$\nabla G(f) = \begin{cases} 0 & 0 < f < 10^{1} \\ -20 & 10 < f < 10^{2} \\ -60 & 10^{2} < f < 10^{3} \\ -40 & 10^{3} < f < 10^{4} \\ 0 & 10^{4} < f < 10^{5} \\ -40 & 10^{5} < f < 10^{6} \\ -60 & 10^{6} < f < 10^{7} \end{cases}$$
 (2.2.2)

2.3. Express the change of slope of G(f) in terms of f.

Solution:

 $\Delta(\nabla G(f))$ = Change of slope G(f) at f

	(-20)	$f = 10^1$	
	-40	$f = 10^2$	
$\Lambda(\nabla C(f)) =$	+20	$f = 10^3$	(2.2.1)
$\Delta(\mathbf{VG}(f)) = 0$	+40	$f = 10^4$	(2.3.1)
	-40	$f = 10^5$	
$\Delta(\nabla G(f)) = \cdot$	(-20)	$f = 10^6$	

2.4. Tabulate the poles and zeros of H(s) using (2.3.1).

Solution: Table 2.4 provides the details.

f (Hz)	$\Delta \left(\nabla G(f) \right)$	Pole	Zero
10^{1}	-20	1	0
10^{2}	-40	2	0
10^{3}	20	0	1
10^{4}	40	0	2
10^{5}	-40	2	0
10^{6}	-20	1	0
Total		6	3

TABLE 2.4

2.5. Obtain the transfer function of H(s). **Solution:** From Table 2.4,

$$H(s) = \frac{K(s+j2\pi10^3)(s+j2\pi10^4)^2}{(s+j2\pi10^1)(s+j2\pi10^2)^2(s+j2\pi10^5)^2(s+j2\pi10^6)} \tag{2.5.1}$$

2.6. Justify the above results.

Solution: Let us consider a generalized transfer gain

$$H(s) = k \frac{(s-z_1)(s-z_2)...(s-z_{m-1})(s-z_m)}{(s-p_1)(s-p_2)....(s-p_{n-1})(s-p_n)}$$
(2.6.1)

The gain

$$G(f) = 20 \log |H(s)|$$

$$= 20 \log |k| + 20 \log |s - z_1|$$

$$+ 20 \log |s - z_2| + \dots + 20 \log |s - z_m|$$

$$- 20 \log |s - p_1| - 20 \log |s - p_2|$$

$$- \dots - 20 \log |s - z_n| \quad (2.6.2)$$

Substituting $s = j\omega$, for real z_1

$$20 \log |s - z_1| = 20 \log \left| \sqrt{\omega^2 + z_1^2} \right| \qquad (2.6.3)$$

$$= \begin{cases} 20 \log |z_1|, & \omega \ll z_1 \\ 20 \log |\omega|, & \omega \gg z_1 \end{cases} \qquad (2.6.4)$$

Taking the derivative,

$$\frac{d\left(20\log|s-z_1|\right)}{d\left(\log|\omega|\right)} = \begin{cases} 0, & \omega \ll z_1\\ 20, & \omega \gg z_1 \end{cases}$$
 (2.6.5)

Thus, when a zero is encountered, the gradient of $H(j\omega)$ jumps by +20 in the log scale. When a pole is encountered, the gradient falls by -20. Note that this is a very loose justification, but works well in practice.

2.7. Obtain the Bode plot and the slope plot for 2.2.6. Obtain the Bode plot of G(s) through a python H(s) and verify with Fig. 2.1 code and compare with the line plot of the

Solution: Bode Plot of obtained Transfer Func- expression that you obtained in Problem 2.2.1 tion is Fig. ??, obtained from , is a close 2.2.7. Verify if at very high frequency $(\omega \to \infty)$, the

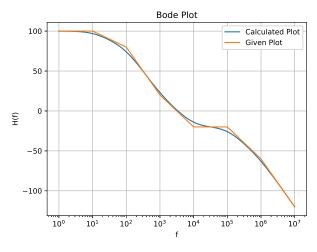

Fig. 2.7

reconstruction of Fig. ??.

2.2 Example

- 2.2.1. The asymptotic Bode magnitude plot of minimum phase transfer function G(s) is show below. Express $20 \log |G(j\omega)|$ as a function of ω using Fig. 2.2.1.
- 2.2.2. Express the slope of $20 \log |G(j\omega)|$ as a function of ω .
- 2.2.3. Express the change of slope of $20 \log |G(j\omega)|$ as a function of ω .
- 2.2.4. Find the poles and zeros of G(s).

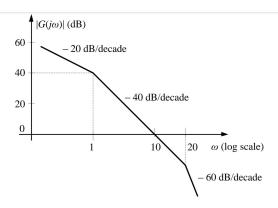

Fig. 2.2.1

2.2.5. Find G(s)

Obtain the Bode plot of G(s) through a python code and compare with the line plot of the expression that you obtained in Problem 2.2.1 Verify if at very high frequency $(\omega \to \infty)$, the phase angle $\angle G(j\omega) = -3\pi/2$ Solution: Since, each pole corresponds to -20 dB/decade and each zero corresponds to +20 dB/decade. Therefore, from the given Bode plot we can get the Transfer equation,

$$G(s) = \frac{k}{s(1+s)(20+s)}$$
 (2.2.7.1)

Now, from the Transfer equation we can conclude that, there are three poles (0, -1 and -20) and no zeros.

:. Statement 1 is false(1)

Calculating phase:

Since we know that,

phase ϕ is the sum of all the phases corresponding to each pole and zero. phase corresponding to pole is =

$$-tan^{-1}(\frac{imaginary}{real}) (2.2.7.2)$$

phase corresponding to zero is =

$$tan^{-1}(\frac{imaginary}{real})$$
 (2.2.7.3)

Now take,

$$s = j\omega \tag{2.2.7.4}$$

$$\Rightarrow G(j\omega) = \frac{k}{j\omega(1+j\omega)(20+j\omega)} \quad (2.2.7.5)$$

Therefore,

$$\phi = -tan^{-1}(\frac{\omega}{0}) - tan^{-1}(\omega) - tan^{-1}(\frac{\omega}{20})$$
(2.2.7.6)

$$\phi = -90^{\circ} - \tan^{-1}(\omega) - \tan^{-1}(\frac{\omega}{20}) \quad (2.2.7.7)$$

$$: \omega \to \infty \tag{2.2.7.8}$$

$$\phi = -90^{\circ} - 90^{\circ} - 90^{\circ} \tag{2.2.7.9}$$

$$\phi = -270^{\circ} \tag{2.2.7.10}$$

$$\phi = -3\pi/2 \tag{2.2.7.11}$$

:. Statement 2 is true(2) thus, from (1) and (2) option (B) is correct. **Solution:** For

$$H(s) = \frac{25}{s^2 + 10s + 25},$$
 (3.1.2.1)

$$\omega^2 = 25, 2\zeta\omega = 10 \tag{3.1.2.2}$$

$$\implies \omega = 1, \zeta = 1$$
 (3.1.2.3)

and the system is critically damped. Similarly, the damping factors for other systems in Problem 3.1.2 are calculated and listed in Table 3.1.2

H(s)	ω	ζ	Damping Type
$\frac{35}{s^2 + 18s + 35}$	$\sqrt{35}$	$\sqrt{\frac{81}{35}} > 1$	Overdamped
$\frac{25}{s^2+10s+25}$	5	1	Critically Damped
$\frac{15}{s^2 + 5s + 15}$	$\sqrt{15}$	$\sqrt{\frac{5}{12}} < 1$	Underdamped

TABLE 3.1.2

2.2.8.

3 Second order System

- 3.1 Damping
- 3.1.1. List the different kinds of damping for a second order system defined by

$$H(s) = \frac{\omega^2}{s^2 + 2\zeta\omega + \omega^2}$$
 (3.1.1.1)

where ω is the natural frequency and ζ is the damping factor.

Solution: The details are available in Table 3.1.1

Damping Ratio	Damping Type
$\zeta > 1$	Overdamped
$\zeta = 1$	Critically Damped
$0 < \zeta < 1$	Underdamped
$\zeta = 0$	Undamped

TABLE 3.1.1

- 3.1.2. Classify the following second-order systems according to damping.
 - a) $H(s) = \frac{15}{s^2 + 5s + 15}$ b) $H(s) = \frac{25}{s^2 + 10s + 25}$ c) $H(s) = \frac{35}{s^2 + 18s + 35}$

- 3.1.3. By choosing an appropriate input, illustrate the effect of damping using a Python code to sketch the response.
- 3.2 Example
- 3.1. Consider the following second order system with the transfer function

$$G(s) = \frac{1}{1 + 2s + s^2}$$
 (3.1.1)

Is the system stable?

Solution: The poles of

$$G(s) = \frac{1}{1 + 2s + s^2}$$
 (3.1.2)

are at

$$s = -1$$
 (3.1.3)

i.e., the left half of s-plane. Hence the system is stable.

- 3.2. Find and sketch the step response c(t) of the system.
 - **Solution:** For step-response, we take input as

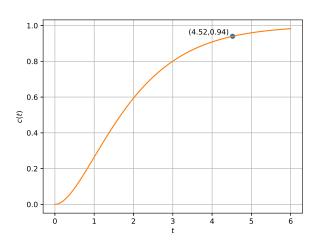

Fig. 3.2

Using 3.2.5,

$$\lim_{t \to \infty} c(t) = \lim_{t \to \infty} (1 - e^{-t} - te^{-t}) u(t)$$
 (3.3.3)

$$= (1 - 0 - 0) = 1 \tag{3.3.4}$$

3.4. Find the time taken for the system output c(t)to reach 94% of its steady state value.

Solution: Now, 94% of 1 is 0.94, so we should now solve for a positive t such that

$$1 - e^{-t} - te^{-t} = 0.94 (3.4.1)$$

The following code

Solution:

codes/ee18btech11002/solution.py

provides the necessary solution as

$$t = 4.5228 \tag{3.4.2}$$

unit-step function u(t)

$$C(s) = U(s).G(s) = \left[\frac{1}{s}\right] \left[\frac{1}{1+2s+s^2}\right]$$

(3.2.2)

4.1 Routh Array (3.2.1) 4.1.1. Generate the Routh array for the polynomial,

4 ROUTH HURWITZ CRITERION

$$f(s) = s^7 + s^6 + 7s^5 + 14s^4 + 31s^3 + 73s^2 + 25s + 200$$
(4.1.1.1)

 $=\frac{1}{s(1+s)^2}$ $=\frac{1}{s}-\frac{1}{(1+s)}-\frac{1}{(1+s)^2}$

Taking the inverse Laplace transform,

$$c(t) = L^{-1} \left[\frac{1}{s} \right] - L^{-1} \left[\frac{1}{1+s} \right] - L^{-1} \left[\frac{1}{(1+s)^2} \right]$$
(3.2.4)

$$= (1 - e^{-t} - te^{-t}) u(t)$$
 (3.2.5)

The following code plots c(t) in Fig. 3.2

codes/ee18btech11002/plot.py

 $\begin{vmatrix} s' \\ s^6 \\ s^5 \end{vmatrix} \begin{vmatrix} 1 & 7 & 31 & 25 \\ 1 & 14 & 73 & 200 \\ -7 & -42 & -175 & 0 \end{vmatrix}$ (4.1.1.2)

$$\begin{vmatrix} s^7 \\ s^6 \\ s^5 \\ s^4 \end{vmatrix} \begin{vmatrix} 1 & 7 & 31 & 25 \\ 1 & 14 & 73 & 200 \\ -7 & -42 & -175 & 0 \\ 8 & 48 & 200 & 0 \end{vmatrix}$$
 (4.1.1.3)

$$\begin{vmatrix}
s^7 \\ s^6 \\ s^5 \\ s^5 \\ -7 & -42 & -175 & 0 \\ 8 & 48 & 200 & 0 \\ s^3 \\ 0 & 0 & 0 & 0
\end{vmatrix}$$
(4.1.1.4)

3.3. Find the steady state response of the system using the final value theorem. Verify using 3.2.5

Solution: To know the steady response value of c(t), using final value theorem,

$$\lim_{t \to \infty} c(t) = \lim_{s \to 0} sC(s) \tag{3.3.1}$$

We get

$$\lim_{s \to 0} s \left(\frac{1}{s}\right) \left(\frac{1}{1+s+s^2}\right) = \frac{1}{1+0+0} = 1$$
(3.3.2)

When such a case is encountered, we take the derivative of the expression formed the the coefficients above it i.e derivative of $8s^4+48s^2+$ 200.

$$\frac{d}{ds}(8s^4 + 48s^2 + 200) = 32s^3 + 96s$$

The coefficients of obtained expression are placed in the table.

$$\begin{vmatrix} s^{7} \\ s^{6} \\ s^{5} \\ s^{4} \\ s^{3} \end{vmatrix} \begin{vmatrix} 1 & 7 & 31 & 25 \\ 1 & 14 & 73 & 200 \\ -7 & -42 & -175 & 0 \\ 8 & 48 & 200 & 0 \\ 32 & 96 & 0 \end{vmatrix}$$
 (4.1.1.5)

$$\begin{vmatrix} s^7 \\ s^6 \\ s^5 \\ s^4 \end{vmatrix} \begin{vmatrix} 1 & 7 & 31 & 25 \\ 1 & 14 & 73 & 200 \\ -7 & -42 & -175 & 0 \\ 8 & 48 & 200 & 0 \end{vmatrix}$$

96

$$\begin{vmatrix} s^{7} \\ s^{6} \\ s^{5} \\ s^{5} \\ s^{4} \end{vmatrix} = \begin{vmatrix} 1 & 7 & 31 & 25 \\ 1 & 14 & 73 & 200 \\ -7 & -42 & -175 & 0 \\ 8 & 48 & 200 & 0 \\ 8^{3} \\ s^{3} \\ s^{2} \\ s^{1} \\ -170.67 & 0 \end{vmatrix}$$
(4.1.1.7)

0

$$\begin{vmatrix} s^{7} \\ s^{6} \\ s^{5} \\ s^{4} \\ s^{3} \\ s^{2} \\ s^{0} \end{vmatrix} = \begin{vmatrix} 1 & 7 & 31 & 25 \\ 1 & 14 & 73 & 200 \\ -7 & -42 & -175 & 0 \\ 8 & 48 & 200 & 0 \\ 32 & 96 & 0 \\ 24 & 200 & 0 \\ -170.67 & 0 \\ 200 \end{vmatrix}$$
(4.1.1.8)

So, the above one is the Routh-Hurwitz Table.

4.1.2. Find the number of roots of the polynomial in 4.2.2. Find the *characteristic* equation for G(s). the right half of the s-plane.

Solution: The number of roots of the polynomial that are in the right half-plane is equal to the number of sign changes in the first column. From 4.1.1.8, the polynomial in (4.1.1.1) has 4 roots lie on right-side of Imaginary Axis.

4.1.3. Write a Python code for generating each stage of the Routh Table.

Solution: The following code

codes/ee18btech11014/ee18btech11014.py

generates the various stages.

4.1.4. Find the roots of the polynomial in in (4.1.1.1) and verify that 4 roots are in the right half splane.

> Solution: The following code generates the necessary roots.

codes/ee18btech11014/Roots.py

4.2.1. Consider a unity feedback system as shown in Fig. 4.2.1, with an integral compensator $\frac{k}{\epsilon}$ and (4.1.1.6)open-loop transfer function

$$G(s) = \frac{1}{s^2 + 3s + 2} \tag{4.2.1.1}$$

where k greater than 0. Find its closed loop transfer function.

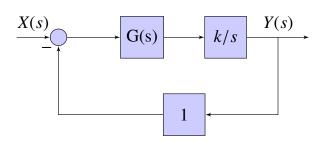

Fig. 4.2.1

Solution: H(s) = 1 in Fig. 4.2.1, due to unity feedback, the transfer function is given by

$$\frac{Y(s)}{X(s)} = \frac{G(s)}{1 + G(s)H(s)}$$
(4.2.1.2)

$$\implies T(s) = \frac{k}{s^3 + 3s^2 + 2s}$$
 (4.2.1.3)

Solution: The characteristic equation is

$$1 + G(s)H(s) = 0 (4.2.2.1)$$

$$\implies 1 + \left[\frac{k}{s^3 + 3s^2 + 2s}\right] = 0$$
 (4.2.2.2)

or,
$$s^3 + 3s^2 + 2s + k = 0$$
 (4.2.2.3)

4.2.3. Using the tabular method for the Routh hurwitz criterion, find k > 0 for which there are two poles of unity feedback system on $j\omega$ axis.

> **Solution:** This criterion is based on arranging the coefficients of characteristic equation into

an array called Routh array. For any characteristic equation

$$q(s) = a_0 s^n + a_1 s^{n-1} + \dots + a_{n-1} s + a_n = 0$$
(4.2.3.1)

the Routh array can be constructed as

$$\begin{vmatrix} s^{n} \\ s^{n-1} \\ s^{n-2} \\ \vdots \end{vmatrix} \begin{vmatrix} a_{0} & a_{2} & a_{4} & \cdots \\ a_{1} & a_{3} & a_{5} & \cdots \\ b_{1} & b_{2} & b_{3} & \cdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \cdots \end{vmatrix}$$
(4.2.3.2)

where

method.

$$b_1 = \frac{a_1 a_2 - a_0 a_3}{a_2} \tag{4.2.3.3}$$

$$b_1 = \frac{a_1 a_2 - a_0 a_3}{a_1}$$
 (4.2.3.3)
$$b_2 = \frac{a_1 a_4 - a_0 a_5}{a_1}$$
 (4.2.3.4)

$$c_1 = \frac{b_1 a_3 - a_1 b_2}{b_1} \tag{4.2.3.5} 4.2$$

$$c_2 = \frac{b_1 a_5 - a_1 b_3}{b_1} \tag{4.2.3.6}$$

For poles to lie on imaginary axis any one entire row of hurwitz matrix should be zero. Constructing the routh array for the characteristic equation obtained in 4.2.2.1,

$$s^3 + 3s^2 + 2s + k = 0 (4.2.3.7)$$

$$\begin{vmatrix} s^{3} \\ s^{2} \\ s^{1} \\ s^{0} \end{vmatrix} \begin{vmatrix} 1 & 2 \\ 3 & k \\ \frac{6-k}{3} & 0 \\ k & 0 \end{vmatrix}$$
 (4.2.3.8)

For poles on 1ω axis any one of the row should be zero.

$$\therefore \frac{6-k}{3} = 0 \text{ or } k = 0$$
 (4.2.3.9)

$$\implies k = 6 \quad \because k > 0$$
 (4.2.3.10)

4.2.4. Repeat the above using the determinant

Solution: The *Routh matrix* can be expressed as

$$\mathbf{R} = \begin{pmatrix} a_0 & a_2 & a_4 & \cdots \\ a_1 & a_3 & a_5 & \cdots \\ 0 & a_0 & a_2 \cdots \\ 0 & a_1 & a_3 \cdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \cdots \end{pmatrix}$$
(4.2.4.1)

and the corresponding Routh determinants are

$$D_1 = |a_0| \tag{4.2.4.2}$$

$$D_2 = \begin{vmatrix} a_0 & a_2 \\ a_1 & a_3 \end{vmatrix} \tag{4.2.4.3}$$

$$D_{2} = \begin{vmatrix} a_{0} & a_{2} \\ a_{1} & a_{3} \end{vmatrix}$$
 (4.2.4.3)

$$D_{3} = \begin{vmatrix} a_{0} & a_{2} & a_{4} \\ a_{1} & a_{3} & a_{5} \\ 0 & a_{0} & a_{2} \end{vmatrix}$$
 (4.2.4.4)

If at least any one of the Determinents are zero then the poles lie on imaginary axes. From (4.2.2.1),

$$D_1 = 1 \neq 0 \tag{4.2.4.6}$$

$$D2 = \begin{vmatrix} 1 & 2 \\ 3 & k \end{vmatrix} = k - 6 = 0 \implies k = 6$$
(4.2.4.7)

(4.2.3.5) 4.2.5. Verify your answer using a python code for both the determinant method as well as the tabular method.

> **Solution:** The following code verifies the stability using the tabular method

and the following one verifies using the determinant method.

codes/ee18btech11005.py

provides the necessary soution.

- For the system to be stable all coefficients should lie on left half of s-plane. Because if any pole is in right half of s-plane then there will be a component in output that increases without bound, causing system to be unstable. All the coefficients in the characteristic equation should be positive. This is necessary condition but not sufficient. Because it may have poles on right half of s plane. Poles are the roots of the characteristic equation.
- A system is stable if all of its characteristic modes go to finite value as t goes to infinity. It is possible only if all the poles are on the left half of s plane. The characteristic equation should have negative roots only. So the first column should always be greater than zero. That means no sign changes.
- A system is unstable if its characteristic modes are not bounded. Then the characteristic equation will also have roots in the

right side of s-plane. That means it has sign changes.

4.3 Stability

4.3.1. The characteristic equation of linear time invariant system is given by

$$\nabla(s) = s^4 + 3s^3 + 3s^2 + s + k = 0 \quad (4.3.1.1)$$

Find the condition for the system to be BIBO stable using the Routh Array.

solution

$$\nabla(s) = s^4 + 3s^3 + 3s^2 + s + k = 0 \quad (4.3.1.2)$$

The Routh hurwitz criterion:-

$$\begin{vmatrix} s^{4} \\ s^{3} \\ s^{2} \\ s^{1} \\ s^{0} \end{vmatrix} \begin{vmatrix} 1 & 3 & k \\ 3 & 1 & 0 \\ \frac{8}{3} & k & 0 \\ \frac{\frac{8}{3} - 3k}{8} & 0 & 0 \\ k & 0 & 0 \end{vmatrix}$$
 (4.3.1.3)

From the above array, the given system is stable if

$$\frac{k > 0}{\frac{8}{3} - 3k} > 0$$

$$\implies 0 < k < \frac{8}{9}$$
(4.3.1.4)
$$(4.3.1.5)$$

4.3.2. Modify the Python code in Problem 4.2.5 to verify your solution by choosing two different values of k.

Solution: The following code

provides the necessary soution for k = 0.5, 3.

- $k = 0.5 < \frac{8}{9}$ has no sign changes in first column of its routh array. So the system is stable
- $k = 3 > \frac{8}{9}$ has 2 sign changes in first column of its routh array. So the system is unstable.

5 STATE-SPACE MODEL

- 5.1 Controllability and Observability
- 5.1. State the general model of a state space system specifying the dimensions of the matrices and

vectors.

Solution: The model is given by

$$\dot{\mathbf{x}}(t) = \mathbf{A}\mathbf{x}(t) + \mathbf{B}\mathbf{u}(t) \tag{5.1.1}$$

$$\mathbf{y}(t) = \mathbf{C}\mathbf{x}(t) + \mathbf{D}\mathbf{u}(t) \tag{5.1.2}$$

with parameters listed in Table 5.1.

Variable	Size	Description
u	$p \times 1$	input(control)
		vector
y	$q \times 1$	output vector
X	$n \times 1$	state vector
A	$n \times n$	state or system
		matrix
В	$n \times p$	input matrix
C	$q \times n$	output matrix
D	$q \times p$	feedthrough
		matrix

TABLE 5.1

5.2. Find the transfer function $\mathbf{H}(s)$ for the general system.

Solution: Taking Laplace transform on both sides we have the following equations

$$sIX(s) - x(0) = AX(s) + BU(s)$$
 (5.2.1)

$$(s\mathbf{I} - \mathbf{A})\mathbf{X}(s) = \mathbf{B}\mathbf{U}(s) + \mathbf{x}(0)$$
 (5.2.2)

$$\mathbf{X}(s) = (s\mathbf{I} - \mathbf{A})^{-1}\mathbf{B}\mathbf{U}(s) \qquad (5.2.3)$$

$$+ (s\mathbf{I} - \mathbf{A})^{-1}\mathbf{x}(0)$$
 (5.2.4)

and

$$\mathbf{Y}(s) = \mathbf{CX}(s) + D\mathbf{IU}(s) \tag{5.2.5}$$

Substituting from (5.2.4) in the above,

$$\mathbf{Y}(s) = (\mathbf{C}(s\mathbf{I} - \mathbf{A})^{-1}\mathbf{B} + D\mathbf{I})\mathbf{U}(s) + \mathbf{C}(s\mathbf{I} - \mathbf{A})^{-1}\mathbf{x}(0) \quad (5.2.6)$$

5.3. Find H(s) for a SISO (single input single output) system.

Solution:

$$H(s) = \frac{Y(s)}{U(s)} = \mathbf{C}(s\mathbf{I} - \mathbf{A})^{-1}\mathbf{B} + D\mathbf{I} \quad (5.3.1)$$

5.4. Given

$$H(s) = \frac{1}{s^3 + 3s^2 + 2s + 1}$$
 (5.4.1)

$$D = 0 \tag{5.4.2}$$

$$\mathbf{B} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \tag{5.4.3}$$

find **A** and **C** such that the state-space realization is in *controllable canonical form*.

Solution:

$$\therefore \frac{Y(s)}{U(s)} = \frac{Y(s)}{V(s)} \times \frac{V(s)}{U(s)}, \tag{5.4.4}$$

letting

$$\frac{Y(s)}{V(s)} = 1, (5.4.5)$$

results in

$$\frac{U(s)}{V(s)} = s^3 + 3s^2 + 2s + 1 \tag{5.4.6}$$

giving

$$U(s) = s^{3}V(s) + 3s^{2}V(s) + 2sV(s) + V(s)$$
(5.4.7)

so the above equation can be written as

$$\begin{pmatrix} sV(s) \\ s^2V(s) \\ s^3V(s) \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -1 & -2 & -3 \end{pmatrix} \begin{pmatrix} V(s) \\ sV(s) \\ s^2V(s) \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} U$$
 (5.4.8)

Letting

$$\mathbf{A} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -1 & -2 & -3 \end{pmatrix} \tag{5.4.9}$$

$$\mathbf{X}_1 = \begin{pmatrix} sV(s) \\ s^2V(s) \\ s^3V(s) \end{pmatrix}$$
 (5.4.10)

$$\mathbf{X} = \begin{pmatrix} V(s) \\ sV(s) \\ s^2V(s) \end{pmatrix}, \tag{5.4.11}$$

$$\mathbf{X}_1(s) = \mathbf{A}\mathbf{X}(s) + \mathbf{B}U(s) \tag{5.4.12}$$

$$Y = \mathbf{CX}_1(s) \tag{5.4.13}$$

where

$$\mathbf{C} = \begin{pmatrix} 1 & 0 & 0 \end{pmatrix} \tag{5.4.14}$$

5.5. Obtain **A** and **C** so that the state-space realization in in *observable canonical form*.

Solution: Given that

$$H(s) = \frac{1}{s^3 + 3s^2 + 2s + 1},$$
 (5.5.1)

$$\frac{Y(s)}{U(s)} = \frac{1}{s^3 + 3s^2 + 2s + 1}$$
 (5.5.2)

$$\implies U(s) = Y(s)(s^3 + 3s^2 + 2s + 1)$$
 (5.5.3)

or,
$$Y(s) = -3s^{-1}Y(s) - 2s^{-2}Y(s) +$$

 $s^{-3}(U(s) - Y(s))$ (5.5.4)

Let

$$X_1(s) = Y(s) = -3s^{-1}Y(s) - 2s^{-2}Y(s) + s^{-3}(U(s) - Y(s))$$
(5.5.5)

$$X_2(s) = -2s^{-1}Y(s) + s^{-2}(U(s) - Y(s)) \quad (5.5.6)$$

$$X_3(s) = s^{-1}(U(s) - Y(s))$$
 (5.5.7)

$$sX_1(s) = -3Y(s) + X_2(s)$$

 $\implies sX_2(s) = -2Y(s) + X_3(s)$ (5.5.8)
 $sX_3(s) = U(s) - Y(s)$

Substituting $Y = X_1(s)$ the above,

$$sX_1(s) = -3X_1(s) + X_2(s)$$
 (5.5.9)

$$sX_2(s) = -2X_1(s) + X_3(s)$$
 (5.5.10)

$$sX_3(s) = U(s) - X_1(s)$$
 (5.5.11)

which can be expressed as

$$\begin{pmatrix} sX_1(s) \\ sX_2(s) \\ sX_3(s) \end{pmatrix} = \begin{pmatrix} -3 & 1 & 0 \\ -2 & 0 & 1 \\ -1 & 0 & 0 \end{pmatrix} \begin{pmatrix} X_1(s) \\ X_2(s) \\ X_3(s) \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} U$$
(5.5.12)

or,
$$s\mathbf{X}(s) = \mathbf{A}\mathbf{X}(s) + \mathbf{B}U(s)$$

 $Y(s) = \mathbf{B}\mathbf{X}(s)$ (5.5.13)

where

$$\mathbf{A} = \begin{pmatrix} -3 & 1 & 0 \\ -2 & 0 & 1 \\ -1 & 0 & 0 \end{pmatrix} \tag{5.5.14}$$

$$\mathbf{B} = \begin{pmatrix} 1 & 0 & 0 \end{pmatrix} \tag{5.5.15}$$

5.6. Find the eigenvaues of **A** and the poles of H(s) using a python code.

Solution: The following code

codes/ee18btech11004.py

gives the necessary values. The roots are the same as the eigenvalues.

5.7. Theoretically, show that eigenvalues of **A** are the poles of H(s).

Solution: As we know that the characteristic equation is det(sI-A)

$$s\mathbf{I} - \mathbf{A} = \begin{pmatrix} s & 0 & 0 \\ 0 & s & 0 \\ 0 & 0 & s \end{pmatrix} - \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -1 & -2 & -3 \end{pmatrix} \quad (5.7.1)$$
$$= \begin{pmatrix} s & -1 & 0 \\ 0 & s & -1 \\ 1 & 2 & s+3 \end{pmatrix} \quad (5.7.2)$$

$$\implies |s\mathbf{I} - \mathbf{A}| = s(s^2 + 3s + 2) + 1(1) \quad (5.7.3)$$
$$= s^3 + 3s^2 + 2s + 1 \quad (5.7.4)$$

which is the denominator of H(s) in (5.4.1)

- 5.2 Second Order System
- 5.2.1. Consider a state-variable model of a system

$$\begin{pmatrix} \dot{x_1} \\ \dot{x_2} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -\alpha & -2\beta \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \begin{pmatrix} b_1 \\ b_2 \end{pmatrix} r \qquad (5.2.1.1)$$

$$y = \begin{pmatrix} 1 & 0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$
 (5.2.1.2)

where y is the output, and r is the input.

- 5.2.2. List the various state matrices in (5.2.1.1)
- 5.2.3. Find the system transfer function H(s).

Solution: From $(\ref{eq:condition})$ and , (5.3.1), the transfer function for the state space model is

$$H(s) = C(sI - A)^{-1}B + D (5.2.3.1)$$

$$= \frac{\left(1 \quad 0\right) \binom{s + 2\beta \quad 1}{-\alpha \quad s} \binom{b_1}{b_2}}{s(s + 2\beta) + \alpha}$$

$$= \frac{b_1(s + 2\beta) + b_2}{s^2 + 2s\beta + \alpha} (5.2.3.2)$$

$$\implies H(s) = \frac{b_1s}{s^2 + 2s\beta + \alpha} + \frac{2b_1\beta + b_2}{s^2 + 2s\beta + \alpha} (5.2.3.4)$$

5.2.4. Find the Damping ratio ζ and the Undamped natural frequency ω_n of the system.

Solution: Generally for a second order system the transfer function is given by 3.1.1.1

$$H(s) = \frac{\omega_n^2}{s^2 + 2s\zeta\omega_n + \omega_n^2}$$
 (5.2.4.1)

Comparing the denominator of the above with (5.2.3.4),

$$2\zeta\omega_n = 2\beta,\tag{5.2.4.2}$$

$$\omega_n^2 = \alpha \tag{5.2.4.3}$$

$$\implies \zeta = \frac{\beta}{\sqrt{\alpha}}, \omega_n = \sqrt{\alpha}$$
 (5.2.4.4)

 $= \begin{pmatrix} s & -1 & 0 \\ 0 & s & -1 \\ 1 & 2 & s+3 \end{pmatrix}$ (5.7.2) Solution Table 3.1.1, explain how the damping conditions depend upon α and β .

6 Nyouist Plot

6.1. The open loop transfer function of a unity feedback system is given by

$$G(s) = \frac{\pi e^{-0.25s}}{s} \tag{6.1.1}$$

6.2. Find Re $\{G(j\omega)\}\$ and Im $\{G(j\omega)\}\$.

Solution: From (6.1.1),

$$G(j\omega) = \frac{\pi}{\omega} (-\sin 0.25\omega - j\cos 0.25\omega)$$
(6.2.1)

$$\implies \operatorname{Re} \{G(j\omega)\} = \frac{\pi}{\omega} (-\sin 0.25\omega)$$
 (6.2.2)

$$\operatorname{Im}\left\{G(j\omega)\right\} = \frac{\pi}{\omega}(-j\cos 0.25\omega) \qquad (6.2.3)$$

6.3. Sketch the Nyquist plot.

Solution: The Nyquist plot is a graph of Re $\{G(j\omega)\}$ vs Im $\{G(j\omega)\}$. The following python code generates the Nyquist plot in Fig. 6.3

6.4. Find the point at which the Nyquist plot of G(s) passes through the negative real axis

Solution: Nyquist plot cuts the negative real axis at ω for which

$$\angle G(j\omega) = -\pi \tag{6.4.1}$$

From (6.1.1),

$$G(j\omega) = \frac{\pi e^{-\frac{j\omega}{4}}}{j\omega} = \frac{\pi e^{-j(\frac{\omega}{4} + \frac{\pi}{2})}}{\omega}$$
 (6.4.2)

$$\implies \angle G(j\omega) = -\left(\frac{\omega}{4} + \frac{\pi}{2}\right) \tag{6.4.3}$$

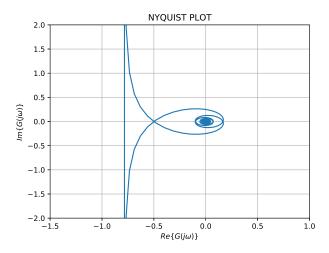

Fig. 6.3

From (6.4.3) and (6.4.1),

$$\frac{\omega}{4} + \frac{\pi}{2} = \pi \tag{6.4.4}$$

$$\implies \omega = 2\pi \tag{6.4.5}$$

Also, from (6.1.1),

$$|G(j\omega)| = \frac{\pi}{|\omega|}$$
 (6.4.6)

$$\implies \left| G(j2\pi) \right| = \frac{1}{2} \tag{6.4.7}$$

6.5. Use the Nyquist Stability criterion to determine if the system in (6.4.3) is stable.

Variable	Value	Description
Z	0	Poles of $\frac{G(s)}{1+G(s)H(s)}$ in right half of s plane
Р	0	Poles of $G(s)H(s)$ in right half of s plane
N	0	No of clockwise encirclements of $G(s)H(s)$ about -1+j0 in the Nyquist plot

TABLE 6.5

Solution: Consider Table 6.5. According to the Nyquist stability criterion,

a) If the open-loop transfer function G(s) has a zero pole of multiplicity l, then the Nyquist plot has a discontinuity at $\omega = 0$. During further analysis it should be assumed that the phasor travels 1 times clock-wise along a

- semicircle of infinite radius. After applying this rule, the zero poles should be neglected, i.e. if there are no other unstable poles, then the open-loop transfer function G(s) should be considered stable.
- b) If the open-loop transfer function G(s) is stable, then the closed-loop system is unstable for any encirclement of the point -1. If the open-loop transfer function G(s) is unstable, then there must be one counter clock-wise encirclement of -1 for each pole of G(s) in the right-half of the complex plane.
- c) The number of surplus encirclements (N + P greater than 0) is exactly the number of unstable poles of the closed-loop system.
- d) However, if the graph happens to pass through the point -1+j0, then deciding upon even the marginal stability of the system becomes difficult and the only conclusion that can be drawn from the graph is that there exist zeros on the $j\omega$ axis.

From (6.1.1), G(s) is stable since it has a single pole at s = 0. Further, from Fig. 6.3, the Nyquist plot doesnot encircle s = -1. From Theorem 6.5b, we may conclude that the system is stable.

7 Compensators

7.1. The Transfer function of Phase Lead Compensator is given by

$$D(s) = \frac{3(s + \frac{1}{3T})}{(s + \frac{1}{T})}$$
 (7.1.1)

Find out the frequency (in rad/sec), at which $\angle D(j\omega)$ is maximum?

Solution: The basic requirement of the phase lead network is that all poles and zeros of the transfer function of the network must lie on negative real axis interlacing each other with a zero located as the nearest point to origin. Substituting $s = i\omega$ in D(s), we get

$$D(j\omega) = \frac{3(j\omega + \frac{1}{3T})}{(j\omega + \frac{1}{T})}$$
 (7.1.2)

The phase of this transfer function $\phi(\omega)$ is given by,

$$\phi(\omega) = \tan^{-1}(3\omega T) - \tan^{-1}(\omega T) \qquad (7.1.3)$$

 $\phi(\omega)$ has its maximum at ω_c Where $\phi'(\omega_c) = 0$,

$$\phi'(\omega_c) = 0 = \frac{3T}{1 + (3\omega_c T)^2} - \frac{T}{1 + (\omega_c T)^2}$$
(7.1.4)

After solving and Simplification, we have

$$\omega_c^2 T^2 = \frac{1}{3} \tag{7.1.5}$$

$$\omega_c = \sqrt{\frac{1}{3T^2}} \tag{7.1.6}$$

7.2. Verify your result through a plot.

Solution: The following plots the Phase value of the transfer function,

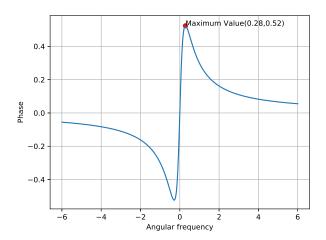

Fig. 7.2

Applications:

- a) Phase lead Compensators can be used as High pass filters, Differentiators.
- b) They are used to reduce steady state errors.
- c) Increases Phase Margin, relative stability.
- 7.3. What is purpose of of a Phase Lead Compensator?
- 7.4. Through an example, show how the compensator in Problem 7.1 can be used in a control

system.

8 Phase Margin

8.1. Find the Phase Margin of G(s) in degrees where

$$G(s) = \frac{2}{(s+1)(s+2)}$$
 (8.1.1)

Solution: Phase Margin: It is the difference between phase of the system and -180° at the gain crossover frequency, (the gain crossover frequency being the frequency at which the open-loop gain first reaches 1).

Phase Margin is given by,

$$P.M = \phi - \angle G(j\omega)|_{\omega = \omega_{nc}} = \phi + 180^{\circ}$$
 (8.1.2)

where,

$$\phi = \angle G(j\omega)|_{\omega = \omega_{gc}} \tag{8.1.3}$$

 ω_{pc} is the Phase crossover frequency (The frequency at which the phase of open-loop transfer function reaches -180°).

 ω_{gc} is the Gain crossover frequency (The frequency at which the gain of the open-loop transfer fuction reaches 1).

Given,

$$G(s) = \frac{2}{(s+1)(s+2)}$$
 (8.1.4)

$$G(j\omega) = \frac{1}{(j\omega+1)(j\omega+2)}$$
 (8.1.5)

We can find magnitude and phase as

$$|G(j\omega)| = \frac{2}{(\sqrt{\omega^2 + 1})(\sqrt{\omega^2 + 4})}$$
 (8.1.6)

$$\angle G(j\omega) = -tan^{-1}(\omega) - tan^{-1}(\frac{\omega}{2}) \qquad (8.1.7)$$

We know that, Gain in dB = 0 at $\omega = \omega_{gc}$

$$20log_{10}|G(j\omega_{gc})| = 0 (8.1.8)$$

$$|G(j\omega_{gc})| = 1 \tag{8.1.9}$$

$$\frac{2}{(\sqrt{\omega_{gc}^2 + 1})(\sqrt{\omega_{gc}^2 + 4})} = 1 \tag{8.1.10}$$

Solving we get,

$$\omega_{gc}^2(\omega_{gc}^2 + 5) = 0 (8.1.11)$$

$$\Rightarrow \omega_{gc} = 0, +j\sqrt{5}, -j\sqrt{5}$$
 (8.1.12)

As frequency is a real quantity Hence, $\omega_{gc} \neq \text{Imaginary}$

$$\therefore \omega_{gc} = 0 \tag{8.1.13}$$

From (8.1.3) and (8.1.7)

$$\phi = \angle G(j\omega_{gc}) = -tan^{-1}(\omega_{gc}) - tan^{-1}(\frac{\omega_{gc}}{2})$$
(8.1.14)

$$=> \phi = 0^{\circ}$$
 (8.1.15)

$$\therefore P.M = 180^{\circ} + 0^{\circ} = 180^{\circ}$$
 (8.1.16)

8.2. We can verify the above result using phase plot. The following code plots Fig(8.3)

8.3. The Phase plot is as shown, We can observe

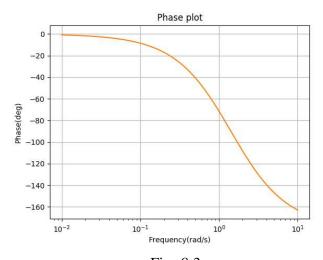

Fig. 8.3

that at $\omega_{gc} = 0$, $\phi = 0^{\circ}$

$$P.M = 180^{\circ}$$
 (8.3.1)

- 8.4. **Application:** Phase margin is measure of stability in closed-loop, dynamic-control systems.(i.e, For stability of a system both gain margin and phase margin should be positive.)
- 8.5. **Example:**Phase Margin is a measure of stability.

Consider a standard second order system with

$$G(s)H(s) = \frac{\omega_n^2}{s(s+2\delta\omega_n)}$$
 (8.5.1)

Sunstituting, $s=j\omega$

$$G(j\omega)H(j\omega) = \frac{\omega_n^2}{(j\omega)(j\omega + 2\delta\omega_n)}$$
(8.5.2)
(8.5.3)

At the gain cross over frequency ω_{gc} , $|G(j\omega)H(j\omega)| = 1$

$$\frac{\omega_n^2}{\omega_{gc}\sqrt{\omega_{gc}^2 + 4\delta^2\omega_n^2}} = 1 \qquad (8.5.4)$$

$$=> \omega_{qc}^4 + 4\delta_2 \omega_{qc}^2 \omega_n^2 - \omega_n^4 = 0 \qquad (8.5.5)$$

Solving we get,

$$\omega_{gc}^2 = \omega_n^2 \sqrt{4\delta^4 + 1} - 2\delta^2 \tag{8.5.6}$$

Phase Margin is given by,

$$P.M = 180^{\circ} + (-90^{\circ} - tan^{-1}(\frac{\omega_{gc}}{2\delta\omega_n}))$$
 (8.5.7)

Further simplifying we get

$$P.M = tan^{-1}(\frac{2\delta\omega_n}{\omega_{gc}})$$
 (8.5.8)

We can observe from (8.5.8) for P.M to be negative

$$1.\delta < 0, \omega_n > 0$$

$$2.\delta > 0, \omega_n < 0$$

For both the cases the pole in the Equation(8.5.1) lie on right half of s-plane. So, the system is unstable.
